ALGORITHMS & ADVANCED DATA STRUCTURES (#10)

DYNAMIC PROGRAMMING

ADAPTED FROM
CS 146 SJSU (KATERINA POTIKA)

Algorithmic Paradigms

- Greed. Build up a solution incrementally, myopically optimizing some local criterion.
- Divide-and-conquer. Break up a problem into two sub-problems, solve each sub-problem independently, and combine solution to sub-problems to form solution to original problem.
- Dynamic programming. Break up a problem into a series of overlapping sub-problems, and build up solutions to larger and larger sub-problems.

Dynamic Programming History

- Bellman. Pioneered the systematic study of dynamic programming in the 1950s.

- Etymology.
  - Dynamic programming = planning over time.
  - Secretary of Defense was hostile to mathematical research.
  - Bellman sought an impressive name to avoid confrontation.
    - "it's impossible to use dynamic in a pejorative sense"
    - "something not even a Congressman could object to"

Reference: Bellman, R. E. *Eye of the Hurricane, An Autobiography.*

Dynamic Programming Applications

- Areas.
  - Bioinformatics.
  - Control theory.
  - Information theory.
  - Operations research.
  - Computer science: theory, graphics, AI, systems, ...

- Some famous dynamic programming algorithms.
  - Viterbi for hidden Markov models.
  - Unix diff for comparing two files.
  - Smith-Waterman for sequence alignment.
  - Bellman-Ford for shortest path routing in networks.
  - Cocke-Kasami-Younger for parsing context free grammars.

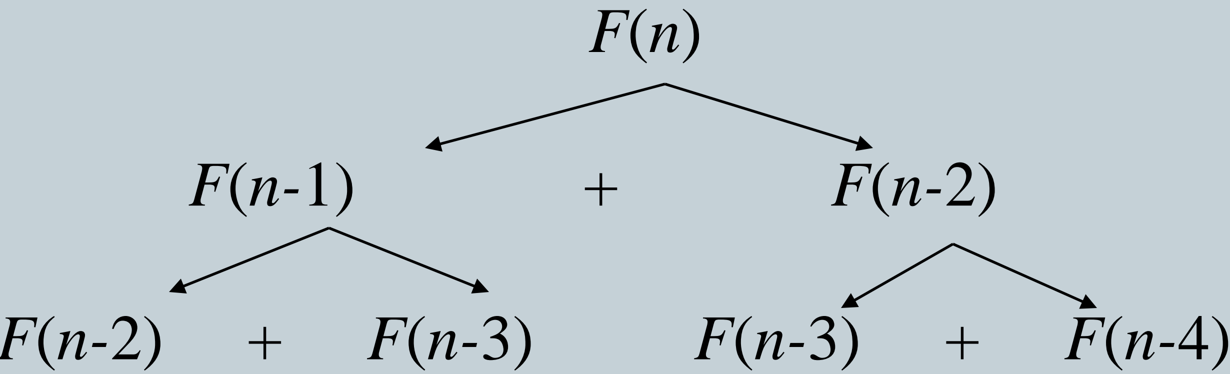
Dynamic Programming – 3rd technique (Ch 15)

- 0-1 Knapsack Problem
- Graph Problems later

Example: Fibonacci numbers

$F(n) = F(n-1) + F(n-2)$
$F(0) = 0$
$F(1) = 1$

- Computing the nth Fibonacci number recursively (top-down):



...

Example: Fibonacci numbers (cont.)

Computing the nth Fibonacci number using bottom-up iteration and recording results:

$F(0) = 0$

$F(1) = 1$

$F(2) = 1+0 = 1$

…

$F(n\text{-}2) =$

$F(n\text{-}1) =$

$F(n) = F(n\text{-}1) + F(n\text{-}2)$

0	**1**	**1**	**. . .**	$\boldsymbol{F(n\text{-}2)}$	$\boldsymbol{F(n\text{-}1)}$	$\boldsymbol{F(n)}$

Efficiency:

- time O(n)
- space O(n)

What if we solve it recursively?

Automated Memoization

- Automated memoization. Many functional programming languages (e.g., Lisp) have built-in support for memoization.

- Q. Why not in imperative languages (e.g., Java)?

```
(defun F (n)
  (if
    (<= n 1)
    n
    (+ (F (- n 1)) (F (- n 2)))))
```

Lisp (efficient)

```
static int F(int n) {
   if (n <= 1) return n;
   else return F(n-1) + F(n-2);
}
```

Java (exponential)

F(40)

F(39) F(38)

F(38) F(37) F(37) F(36)

F(37) F(36) F(36) F(35) F(36) F(35) F(35) F(34)

Dynamic programming

- **Not** a specific algorithm, but a **technique** (like divide-and-conquer).
- Developed back in the day when "programming" meant "tabular method" (like linear programming).
- Used for optimization problems:
  - Find a solution with the optimal value.
  - Minimization or maximization. (We'll see both.)
- Use when problem breaks down into recurring small subproblems
- ***optimal substructure***: optimal solutions to a problem incorporate optimal solutions to related subproblems, which we may solve independently. Bottom up.

Dynamic programming II

- It is used, when the solution can be recursively described in terms of solutions to subproblems (*optimal substructure*)
- Algorithm finds solutions to subproblems and stores them in memory (table) for later use
- More efficient than "*brute-force methods*", which solve the same subproblems over and over again

DP: Four-step method

1. Characterize the **structure** of an optimal solution.
2. **Recursively** define the value of an optimal solution.
3. **Compute** the value of an optimal solution in a **bottom-up** fashion.
4. **Construct** an optimal solution from computed information.

Knapsack problem (Ch 16.2)

- Given some items, pack the knapsack to get the maximum total value.
- Each item has some weight *w_i* and some value *b_i*.
- Total weight that we can carry is no more than some fixed number *W*.
- So we must consider weights of items as well as their value.

Item #	Weight	Value
1	1	8
2	3	6
3	5	5

Knapsack problem

There are two versions of the problem:

(1) "0-1 knapsack problem" and

(2) "Fractional knapsack problem"

(1) Items are indivisible; you either take an item or not. Solved with *dynamic programming*

(2) Items are divisible: you can take any fraction of an item. Solved with a *greedy algorithm*.

0-1 Knapsack problem: a picture

This is a knapsack
Max weight: W = 20

W = 20

Items	Weight w_i	Benefit value b_i
	2	3
	3	4
	4	5
	5	8
	9	10

0-1 Knapsack problem

- Problem, in other words, is to find

$$\max \sum_{i \in T} b_i \text{ subject to } \sum_{i \in T} w_i \leq W$$

  - The problem is called a *"0-1"* problem, because each item must be entirely accepted or rejected.
  - Just another version of this problem is the "*Fractional Knapsack Problem*", where we can take fractions of items.

Solving The Knapsack Problem

- The optimal solution to the fractional knapsack problem can be found with a greedy algorithm
  - Greedy strategy: take in order of dollars/pound

- The optimal solution to the 0-1 problem cannot be found with the same greedy strategy

Counter Example of greedy algorithm

- Consider the 0-1 knapsack problem. What is a good example, with 3 items and W=50, that shows that being greedy does not provide the optimum profit Take the ratio b/w and sort take the two highest (only these fit) is it the best you can do? Or can you choose another pair with higher b's?
- a. w=(10,20,30) and b=(40,100,150)
- b. w=(10,20,30) and b=(70,100,60)
- c. w=(10,20,30) and b=(60,100,120)
- d. none

The Knapsack Problem: Greedy Vs. Dynamic Programming

- The fractional problem can be solved greedily
- The 0-1 problem cannot be solved with a greedy approach
  - however, it can be solved with dynamic programming

The 0-1 Knapsack Problem And Optimal Substructure

- Consider the most valuable load with at most W pounds
  - *If we remove item j from the load of the Knapsack, what do we know about the remaining load?*
  - A: remainder must be the most valuable load weighing at most $W - w_j$ that thief could take from museum, excluding item j

0-1 Knapsack problem: brute-force approach

- Let's first solve this problem with a straightforward algorithm

- Since there are n items, there are 2^n possible combinations of items.
- We go through all combinations and find the one with the most total value and with total weight less or equal to W
- Running time will be $O(2^n)$
- *Is that fast?*

0-1 Knapsack problem: brute-force approach

- Can we do better?
- Yes, with an algorithm based on dynamic programming
- We need to carefully identify the subproblems

Let's try this:
If items are labeled *1..n*, then a subproblem would be to find an optimal solution for
S_k = *{items labeled 1, 2, .. k}*

Defining a Subproblem

If items are labeled *1..n*, then a subproblem would be to find an optimal solution for S_k = *{items labeled 1, 2, .. k}*

- This is a valid subproblem definition.
- The question is: can we describe the final solution (S_n) in terms of subproblems (S_k)?
- Unfortunately, we <u>can't</u> do that. Explanation follows....

Defining a Subproblem

w_1 =2 b_1 =3	w_2 =4 b_2 =5	w_3 =5 b_3 =8	w_4 =3 b_4 =4	

Max weight: W = 20

For S_4:

Total weight: 14;

total benefit: 20

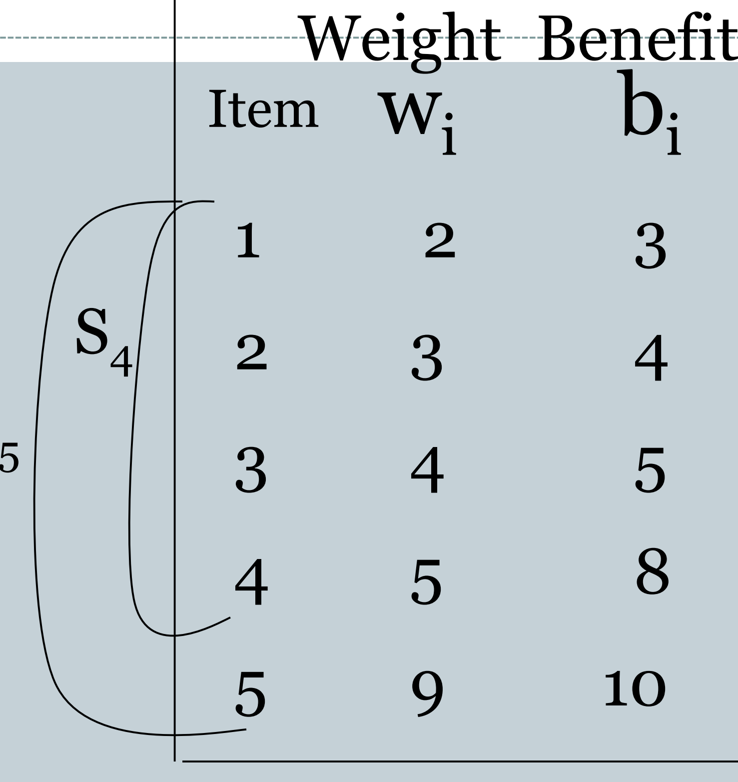
?

w_1 =2 b_1 =3	w_2 =4 b_2 =5	w_3 =5 b_3 =8	w_4 =9 b_4 =10

For S_5:

Total weight: 20

total benefit: 26



Item	Weight w_i	Benefit b_i
1	2	3
2	3	4
3	4	5
4	5	8
5	9	10

Solution for S_4 is not part of the solution for S_5!!!

Defining a Subproblem (continued)

- As we have seen, the solution for S_4 is not part of the solution for S_5
- So our definition of a subproblem is flawed and we need another one!
- Let's add another parameter: *w*, which will represent the exact weight for each subset of items
- **The subproblem then will be to compute *B[k,w]***

Recursive Formula for subproblems

- Recursive formula for subproblems:

$$B[k,w] = \begin{cases} B[k-1,w] & \text{if } w_k > w \\ \max\{ B[k-1,w], B[k-1,w-w_k]+b_k \} & \text{else} \end{cases}$$

- It means, that the best subset of S_k that has total weight w is one of the two:

1) the best subset of S_{k-1} that has total weight w, **or**

2) the best subset of S_{k-1} that has total weight $w-w_k$ plus the item k

Recursive Formula

$$B[k,w]=\begin{cases} B[k-1,w] & \text{if } w_k > w \\ \max\{B[k-1,w], B[k-1,w-w_k]+b_k\} & \text{else} \end{cases}$$

- The best subset of S_k that has the total weight w, either contains item k or not.
- First case: $w_k > w$. Item k can't be part of the solution, since if it was, the total weight would be > w, which is unacceptable
- Second case: $w_k <= w$. Then the item k can be in the solution, and we choose the case with greater value

0-1 Knapsack Algorithm (Exer 16.2-3)

```
for w = 0 to W
  B[0,w] = 0
for i = 0 to n
  B[i,0] = 0
  for w = 0 to W
       if wi <= w // item i can be part of the solution
              if (bi + B[i-1,w-wi] > B[i-1,w])
                     B[i,w] = bi + B[i-1,w- wi]
              else
                     B[i,w] = B[i-1,w]
       else B[i,w] = B[i-1,w]
```

Running time

```
for w = 0 to W
  B[0,w] = 0
for i = 0 to n
  B[i,0] = 0
  for w = 0 to W
      < the rest of the code >
```

O(W)

Repeat *n* times

O(W)

What is the running time of this algorithm?

O(n*W)

Remember that the brute-force algorithm takes $O(2^n)$

Knapsack Problem by DP (example)

Example: Knapsack of capacity $W = 5$

item	weight	profit
1	2	$12
2	1	$10
3	3	$20
4	2	$15

capacity j

	0	1	2	3	4	5
0	0	0	0			
$w_1 = 2, v_1 = 12$ 1	0	0	12			
$w_2 = 1, v_2 = 10$ 2	0	10	12	22	22	22
$w_3 = 3, v_3 = 20$ 3	0	10	12	22	30	32
$w_4 = 2, v_4 = 15$ 4	0	10	15	25	30	37

Backtracing finds the actual optimal subset, i.e. solution.

Example Knapsack

- Let B = [1, 4, 3] and W = [1, 3, 2] be the array of profits and weights the 3 items respectively. Total Weight of knapsack is 4

Longest Common Subsequence (LCS)

- A subsequence of a sequence/string *S* is obtained by deleting zero or more symbols from *S*. For example, the following are some subsequences of "president": pred, sdn, predent. In other words, the letters of a subsequence of S appear in order in *S*, but they are not required to be consecutive.

- The longest common subsequence problem is to find a maximum length common subsequence between two sequences.

LCS

For instance,

Sequence 1: president

Sequence 2: providence

Its LCS is priden.

```
president

providence
```

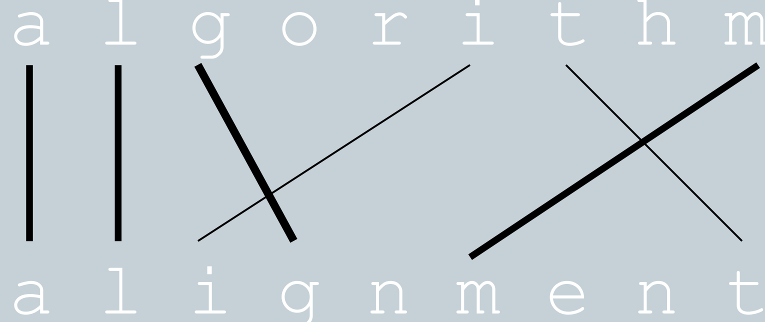
LCS

Another example:

Sequence 1: algorithm

Sequence 2: alignment

One of its LCS is algm.



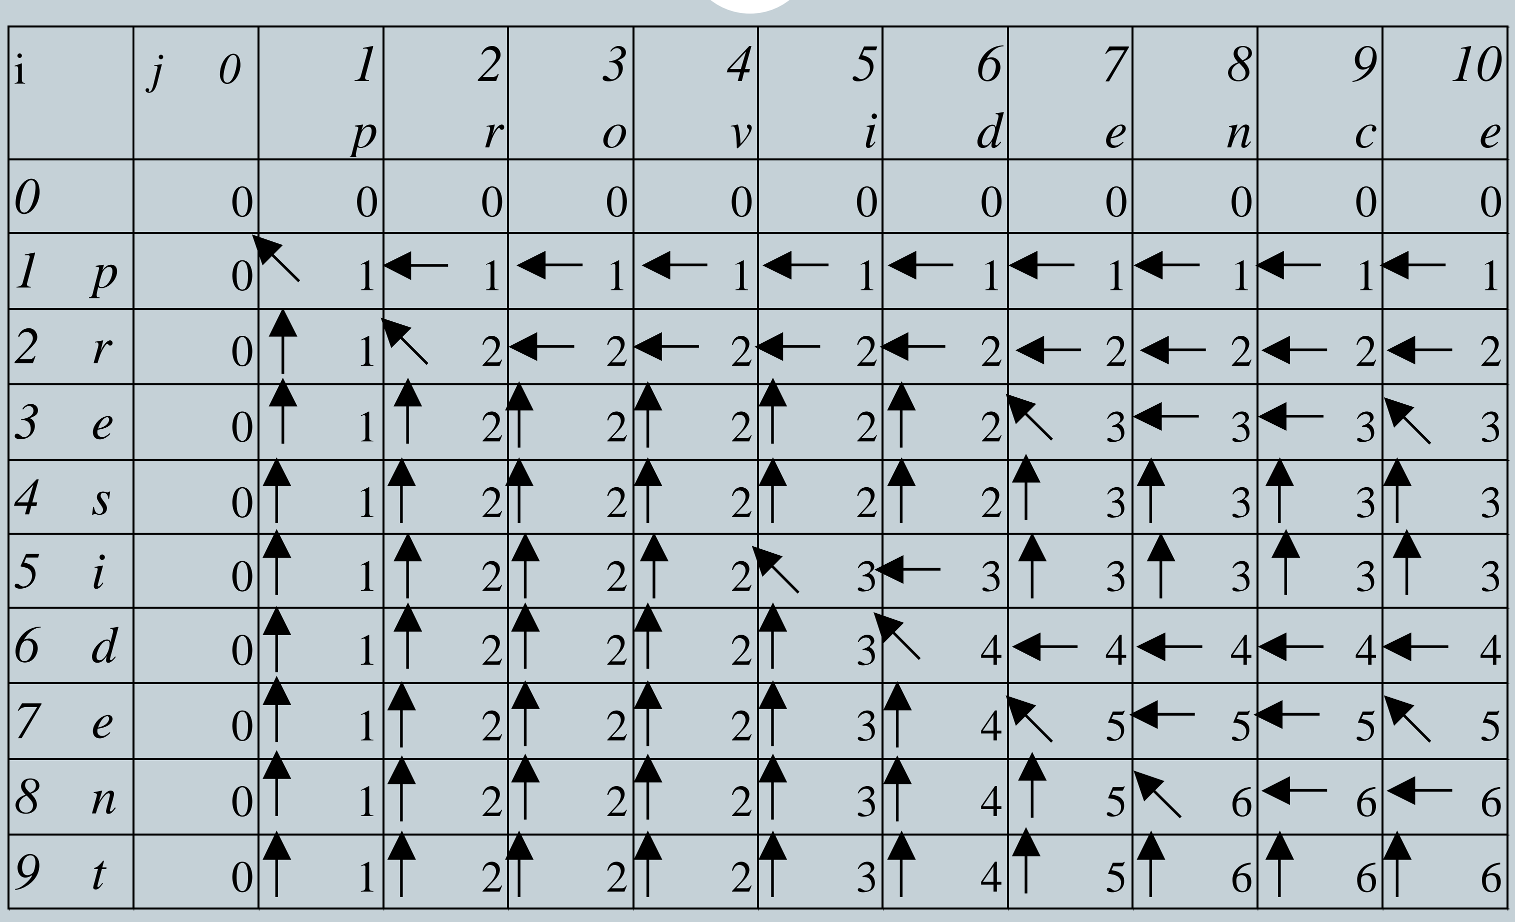
How to compute LCS?

- Let A=$a_1a_2 \ldots a_m$ and $B=b_1b_2 \ldots b_n$.
- $len(i, j)$: the length of an LCS between $a_1a_2 \ldots a_i$ and $b_1b_2 \ldots b_j$
- With proper initializations, $len(i, j)$ can be computed as follows.

$$len(i,j) = \begin{cases} 0 & \text{if } i = 0 \text{ or } j = 0, \\ len(i-1, j-1) + 1 & \text{if } i, j > 0 \text{ and } a_i = b_j, \\ \max(len(i, j-1), len(i-1, j)) & \text{if } i, j > 0 \text{ and } a_i \neq b_j. \end{cases}$$

procedure *LCS-Length(A, B)*

1. **for** $i \leftarrow 0$ **to** m **do** $len(i,0) = 0$
2. **for** $j \leftarrow 1$ **to** n **do** $len(0,j) = 0$
3. **for** $i \leftarrow 1$ **to** m **do**
4. **for** $j \leftarrow 1$ **to** n **do**
5. **if** $a_i = b_j$ **then** $\begin{cases} len(i,j) = len(i-1, j-1) + 1 \\ prev(i,j) = \text{"}\nwarrow\text{"} \end{cases}$
6. **else if** $len(i-1, j) \geq len(i, j-1)$
7. **then** $\begin{cases} len(i,j) = len(i-1, j) \\ prev(i,j) = \text{"}\uparrow\text{"} \end{cases}$
8. **else** $\begin{cases} len(i,j) = len(i, j-1) \\ prev(i,j) = \text{"}\leftarrow\text{"} \end{cases}$
9. **return** *len* and *prev*



i	j 0	1 p	2 r	3 o	4 v	5 i	6 d	7 e	8 n	9 c	10 e
0	0	0	0	0	0	0	0	0	0	0	0

Output: *priden*

In class activity

16.1-4

Suppose that we have a set of activities (lectures) to schedule among a large number of lecture halls, where any activity can take place in any lecture hall. We wish to schedule all the activities using as few lecture halls as possible (minimization problem).

Give an efficient greedy algorithm to determine which activity should use which lecture hall. (This problem is also known as the ***interval-graph coloring problem)***.

We can create an interval graph whose vertices are the given activities and whose edges connect incompatible activities. Draw an example…

The smallest number of colors required to color every vertex so that no two adjacent vertices have the same color corresponds to finding the fewest lecture halls needed to schedule all of the given activities.)

1st attempt

- Use repeated calls to the solution of activity selection algorithm
  - Find a maximum-size set S1 of compatible activities from S for the first lecture hall starting from the beginning,
  - then using it again to find a maximum-size set S2 of compatible activities from S -S1 for the second hall,
  - (and so on until all the activities are assigned), requires Θ(n^2) time in the worst case.
- Is that the optimal (=min #halls)?

- Counterexample: Consider activities with the intervals (1, 4), (2, 5), (6, 7), (4, 8).
  - 1st hall choose the activities (1, 4) and (6, 7) for the first lecture hall, and then each of the activities with intervals
  - Each of (2, 5) and (4, 8) would have to go each into its own hall, for a total of three halls used.
- But optimal solution would put activities (1, 4) and (4, 8) into one

hall and the activities with intervals (2, 5) and (6, 7) into another hall, for only two halls used.

2nd attempt

There is a correct algorithm, however, whose asymptotic time is just the time needed to sort the activities by time

- O(n lg n) time for arbitrary times, or
- possibly as fast as O(n) if the times are small integers.

The general idea is to go through the activities in order of start time, assigning each to any hall that is available at that time. To do this, move through the set of events consisting of activities starting and activities finishing, in order of event time.

Maintain two lists of lecture halls:

1. Halls that are busy at the current event time t (because they have been assigned an activity i that started at $s_i < t$ but won't finish until $f_i > t$) and
2. halls that are free at time t .

How many halls in a optimal solution?

Continue solution

- Sort the 2n activity-starts/activity-ends events. (In the sorted order, an activity ending event should precede an activity-starting event that is at the same hall.)
  - O(n lg n) time for arbitrary times, possibly O(n) if the times are restricted (e.g.,to small range).
- Process the events in O(n) time: Scan the 2n events, doing O(1) work for each (moving a hall from one list to the other and possibly associating an activity with it).
- Total: O(n + time to sort)
